Shoppinglist Generator with Health Advice

PIBA – Software Architecture Lab, WS 2026/27

Team Berlin • Jan, Paul, Pascal, Jenny, Georg, George

Problem

Every human-being has to go grocery shopping but selecting various, changing meals is tedious and people tend to choose the lazy option. Traditional approaches do not factor in personal meal preferences and often result in impulse decisions in the store. However, a ["yolo"] shopping trip may result in lower quality food and can impair the person's health. The decision between healthy food and a cheap purchase can be difficult.

Idea

We want to create an app in which the user can create certain dishes with their ingredients and generate a shopping list based on the user's selection. The ingredients required for a certain dish contain the price, but also certain information about the "healthiness" of the product (E.g. "NutriScore", kCal, Data from the "Nutritional information" table (Nährwerttabelle)). The health data is then analyzed to provide user feedback about the planned shopping trip as well as the expected price.

- Factoren: Preis, Gesundheit, Dauer, Filter (Vegan, Allergie...), - - Gameification - Big Datenbank (chefkoch), manuell vom user? Mock Data - Grob: Akinator - Fein: Swap Left/Right Tinder - Gericht auswahl nach kCal angabe, gewollte eiweiSS, ... - Output: Shopping list für X Gerichte -

- **Recipe Storage** holds all the users dishes with their ingredients which are either created manually or pulled from common public APIs for cooking recipes.
- **Health Evaluation** takes all the information from the single ingredients currently selected for the shopping list and analyzes them. The is done with deterministic algorithms and certain thresholds to decide what degree of healthiness the shopping list or a particular dish has. (Possible AI Integration)
- **Possible Server Integration**: Global database with nutritional information and price for ingredients the clients can pull from.
- **Recommendations**: The app makes dish recommendations for the user based on previous shopping list generations in order to be varied and healthy.

- User: Preferenzen, - WebApp - -

[Main components and their interaction. Architectural style or patterns and why. Driving quality attributes. Out of scope: . . .]

Benefits

- Centralized place for dishes addresses time needed to create shopping list; demonstrated by time taken from selection to finished shopping list
- Nutritional information and analyses addresses unhealthy users eating habits; demonstrated by

Action

1. Specify requirements and develop full architecture with certain user stories.
2. Build core features: Recipe Storage, User Interface, Basic Recipe Management.
3. **Minimum deliverable:** Full web application, recipe support for selection and generating shopping list with ingredients and nutritional information.
4. Extend: Health Analysis, Server Side Database, AI for User recommendations

[Required technologies, data, and infrastructure; team split.]

AI usage statement. None [Which AI tools and models did you use, and for what (e.g. brainstorming, rephrasing)? Write "None" if you did not use AI.]
